THEORY AND EXPERIMENTS ON THE HYPERSONIC SOURCE FLOW OVER LONG, SLENDER BODIES IN A CONICAL NOZZLE

M. Yasuhara, S. Watanabe, H. Mitome and M. Ikeda
Department of Aeronautical Engineering,
Nagoya University, Nagoya, Japan

Abstract

First, inviscid, non-linear, quasi-similarity theory is applied to a long body in a hypersonic source flow, and second, linearized theory for a pointed body is treated by the method of source distribution. These source flow results show large decrease in the surface pressure distribution compared with the parallel ones in the rear part of the body, if the distance from the nose to the body surface normalized by the source-nose distance, increases beyond about 0.1. Third, it is shown that there exists one-to-one correspondence between source flow problem and parallel one in the slender body theory when the ratio $\gamma$ of specific heats of gas is equal to 2. This result, combined with the empirical assumption that the pressure coefficient is insensitive to the difference of the value of $\gamma$, is useful to give an estimation of the pressure distribution over a power-law body in a parallel flow, if the pressure over the modified body in a source flow is obtained theoretically or experimentally, provided that the viscous effect is ignored. Last, pressure distributions along power-law bodies measured in the conical nozzle of a hypersonic shock tunnel are compared with the non-linear theory, and also the source-parallel conversion result, giving essentially good coincidences.

I. Theory

I-A. Quasi-similarity theory

Studies of supersonic source flow past bodies have been of current interests, because these simulate the flow in a divergent section of a hypersonic wind-tunnel, or the one in a central core of the low density free jet, etc. Many of theoretical analyses use Newtonian theory or its modification as given by Hall1, Brun and Guibergia2 etc., while method of characteristics is used by Baradell and Bertram3 and Söveges4 etc. Also, Savage5 and Gorgui6 applied a direct perturbation method to the source flow past wedges or cones, and presented the first order results, which, however, is useful for rather narrow region behind the nose. Yasuhara and Watanabe7 applied the similarity expansion for power-law bodies in the special case of the ratio $\alpha$ and specific heats of 2.0.

The present part deals with the hypersonic source flow past a long slender body by the quasi-similarity approximation.

A-1. Source flow, shock condition, and basic equations

In an inviscid, steady, supersonic flow expanding cylindrically ($\beta$=1) or spherically ($\beta$=1), the flow quantities at a distance $r$ from the effective source, can be obtained from the simple nozzle flow relations. Denote $T_1$ is the temperature, $p_1$ the pressure, $\rho_1$ the density, $u_1$ the radial velocity, $M_1$ the local Mach number in the free stream at radial distance $r$ from the source. Also suffixes "o" and "*" denote quantities at the stagnation and the imaginary sonic point, respectively. The log-log plot of flow quantities against $(r/r_*)^{\beta}$ for $\gamma$=1.4 are shown in Fig.1. For moderately, high values of $M_1$, compared to unity, flow quantities are approximated as follows:

$$
\frac{p_1}{p_N} = s^{-\beta \gamma c}, \quad \frac{\rho_1}{\rho_N} = s^{-\beta c},
$$

$$
\frac{u_1}{u_N} = s^\beta (\epsilon - 1), \quad \frac{M_1}{M_N} = s^{\beta \lambda},
$$

where

$$
\epsilon = \frac{\gamma}{\lambda + 1}, \quad \lambda = \frac{\gamma + 1}{2},
$$

In the above, suffix "N" denotes exact quantities at the nose of the body $r=r_N$ ($s=1$), $\theta=0$. Eq. (1) gives accurate values around $r=r_*$ because the above equations express tangential lines to each curve at $(r_*/r_*)^{\beta}$ in Fig.1. The larger the value of $M_1$, the wider the range of applicability of Eq.(1) is.

Now, as shown in Fig.2, an axisymmetric hypersonic source flow past a slender body with a closed nose, is considered, in which the shock wave is assumed to be attached to the nose of the body at $r=r_N$. The cylindrical or spherical polar coordinates $(r, \theta)$ are used. In this system, the position of the shock and body surface at $r$ are expressed, respectively, by:

212
\theta = \theta^w(r) \, , \quad \phi = \theta^b(r) , \quad (2)

\theta^w = 0 \text{ and } \theta^b = 0 \text{ at } r = r_N^b.

where the subscript "w" and "b" denote quantities just behind the shock wave and along the body surface. With these notations, the shock angle \sigma between the radial ray and the shock line is given by:

\tan \sigma = r d\theta^w / dr = s d\theta^w / ds \equiv s \theta^w , \quad (3)

where "s" denotes the differentiation with respect to s. If \sigma \ll 1, then the quantities just behind the shock wave are given by:

\begin{align*}
p^w = \frac{2\rho_1 u_1^2 \sigma^2}{(y+1)} \left\{ 1 - \frac{\gamma-1}{2\gamma} (M_1 \sigma)^{-2} \right\} , \\
\rho^w = \frac{(y+1) (M_1 \sigma)^2}{2 + (y-1) (M_1 \sigma)^2} , \\
u^w = u_1 - \frac{2u_1 \sigma^2 (M_1 \sigma)^2 - 1}{(y+1) (M_1 \sigma)^2} \equiv \bar{u} , \\
v^w = \frac{2u_1 \sigma (M_1 \sigma)^2 - 1}{(y+1) (M_1 \sigma)^2} ,
\end{align*} \quad (4)

provided that \( M_1 \sigma > 1 \), where \( u \) and \( v \) are the radial and \( \theta \)-wise velocity components, respectively. If \( \theta \) in the disturbed field is very small compared to unity, the basic equations of motion are given by:

\begin{align*}
\frac{1}{r^\theta} \frac{\partial}{\partial \theta} (r^\theta \rho u^2) + \frac{1}{r^\theta \theta^\theta - 1} \frac{\partial}{\partial \theta} (\rho v \theta - 1) = 0 , \\
\frac{\partial}{\partial \theta} u + \frac{v \partial}{r} = = - \frac{\partial}{\partial \theta} (\rho \theta r) , \\
\frac{\partial}{\partial \theta} v + \frac{\partial}{\partial \theta} (uv) + \frac{uv}{r} = - \frac{\partial}{\partial \theta} (\rho \theta) , \\
\frac{\partial}{\partial \theta} \left( \frac{p}{\rho^\gamma} \right) + \frac{v}{r} \left( \frac{p}{\rho^\gamma} \right) = 0 .
\end{align*} \quad (5)

A-2. Quasi-similarity theory

Referring to the shock condition Eq. (6), the independent variables \((r, \theta)\) and flow variables \( p, \rho, u \) and \( v \) are transformed into \((\xi, \eta)\) and \( P, \rho, U \) and \( V \) as follows:

\begin{align*}
\xi = M_1 \sigma \, , \quad \eta = \theta / \theta^w \, , \\
p = \rho_1 u_1^2 \sigma^2 p(\xi, \eta) , \quad \rho = \rho_1 R(\xi, \eta) , \\
u = u_1 U(\xi, \eta) , \quad v = u_1 \sigma V(\xi, \eta) .
\end{align*} \quad (6)

Then, after neglecting smaller quantities of \( 0(\theta^2) \) compared to unity, Eq. (5) is transformed into:

\begin{align*}
& \left( RV \right) \eta - \left( RU \right) \eta + \left( \xi - 1 \right) / \theta R \eta = - \nu \xi U \eta \xi , \\
& \beta (\varepsilon - 1) \omega U \xi^2 + (V - \eta U) U \eta = - \nu \xi U \eta \xi , \\
& \left[ (1 - \beta (\varepsilon - 1) / 2) \omega + \nu \right] RUV \\
& + (V - \eta U) R \eta + P \eta = - \nu \xi UR \xi \eta \xi ,
\end{align*} \quad (7)

\begin{align*}
2 \nu P \xi U \xi^2 + (V - \eta U) (P \eta - \gamma P R \eta) = - \nu \xi (UR \xi \gamma U \eta \xi) ,
\end{align*}

where subscripts "\( \eta \)" and "\( \xi \)" denote partial differentiations with respect to \( \eta \) and \( \xi \) respectively, and:

\begin{align*}
\xi & \equiv M_1 \sigma = N \theta^w \sigma^\theta + 1 , \\
\nu & \equiv \theta^w \xi^\prime / (\theta^w \xi) = (1 + \beta \lambda) \omega + \mu , \\
\omega & \equiv \theta^w \xi^\prime / (s \theta^w) , \quad \mu \equiv \theta^w \omega^w / \theta^w \omega^w .
\end{align*} \quad (8)

Also the shock condition Eq. (4) at \( \eta = 1 \) \((\theta = \theta^w)\), is transformed into:

\begin{align*}
P^w \equiv P(\xi, 1) = \frac{2(2 \xi^2 - \gamma + 1)}{(y+1) 2 \xi^2} , \\
R^w \equiv R(\xi, 1) = \frac{(y+1) \xi^2}{2 + (y-1) \xi^2} , \\
U^w \equiv U(\xi, 1) = 1 , \\
V^w \equiv V(\xi, 1) = \frac{2(\xi^2 - 1)}{(y+1) \xi^2} .
\end{align*} \quad (9)
The other boundary condition at the body surface is given by the tangency of the stream-line and the velocity there, that is:

\[ (V/U)_b = s\theta'_b, \quad \text{or} \quad V_y/U_y = \theta'_b/\theta'_w. \]  

(11)

The similarity solution exists when \( P, R, \) \( U \) and \( V \), including their boundary values at the shock and the body surface, are functions of \( s \) alone. These conditions are satisfied when \( \omega, \nu \) and \( \xi \) given by Eq. (9) are kept constants. At the same time, the following condition must be satisfied:

\[ \theta'_b/\theta'_w = \eta_b = \text{const.} \]  

(12)

Formally, these conditions are satisfied when \( \theta = \theta_x \), which, however, is unrealistic in the present problem, because the condition of the closed nose of the body and the attached shock wave (\( \theta = 0 \) at \( s = 1 \)) cannot be satisfied. The similarity condition for which \( \xi \to \infty \) is the same as shown by Yashurahara.

In general, the similarity conditions can not always be satisfied, and the local similarity approximation is tried here. If all variables along the shock wave and the body surface vary sufficiently slowly with \( s \), then \( \xi, \omega, \nu \) and \( \theta \) in Eq. (8) are assumed to take on their local values at each \( s \). Further, following Oshima's quasi-similarity assumption, \( \xi \)-derivatives in the form \( \xi Q/Q \) in Eq. (8) is evaluated at the shock, \( \xi Q/Q \), that is:

\[ \frac{P_x}{P} = \frac{2(\gamma-1)}{\xi(2\xi^2-\gamma+1)}, \quad \frac{R_x}{R} = \frac{4}{\xi((\gamma-1)\xi^2+2)} \]  

(13)

\[ \frac{U_x}{U} = 0, \quad \frac{V_x}{V} = \frac{2}{\xi(\xi^2-1)}. \]

Use of Eq. (13) in the right-hand terms of Eq. (8) makes the solution more accurate even for values of \( \xi \) not very large compared to unity.

In these manners, Eq. (8) can be regarded as the ordinary differential equations with \( \omega, \nu \) and \( \xi \) as parameters, and thus integrable from the shock to the body surface. The condition Eq. (11) requires some consideration. If \( \theta_b(s) = \theta_w (s) \), then \( \eta_b \) is independent of \( s \), however, in general, \( \eta_b \) is a function of \( s \) through parameters \( \xi, \omega \) and \( \mu \). Thus, using the relation:

\[ \theta'_w = \theta'_b/\eta_b, \]  

(14)

Eq. (11) is expressed in terms of \( \theta_b(s) \) and \( \eta_b(s) \) as

\[ \frac{V}{U_b} = \frac{\theta'_b}{\theta'_w} = 1 - (\eta'_b/\eta_b)(\theta'_b/\theta'_w). \]  

(15)

Unless the term \( \eta'/\eta_b \) is known apriori, the right-hand side of Eq. (15) can not be evaluated as the boundary condition. To express this term as a function of \( s \), an iteration is necessary. With the aid of Eq. (14), \( \omega, \nu \) and \( \xi \) are expressed in terms of \( \theta_b, \eta_b \) and their derivatives with respect to \( s \), that is \( \eta_b, \theta_b' \) and \( \theta_w' \). Now, at the nose of the body \( s = 1 \), \( \theta_b' \) equals to zero and therefore \( \omega = \nu = \xi \) takes some constant value there. Also, assuming several values of \( \eta(s = 1) = \eta_0 \), for example, \( \eta_0 = 0.85, 0.90 \) etc., the corresponding values of \( \xi = \xi \) at \( s = 1 \) are calculated. Then the right-hand sides of Eq. (13) can be calculated. Introducing the above relations into the right-hand side of Eq. (8), the system of ordinary equations for \( P, U, V \) and \( P \) can be integrated for each set of \( (\eta_0, \xi_0) \) from \( s = 1 \) down to \( s = 1 \), where \( V = 0, U = 0 \) holds. The calculated values of \( \eta_0 \) are compared with the assumed values of \( \eta_0 \), and by interpolating and further iterating the procedure, the value of \( \eta_0 \), as well as all values at \( s = 1 \) are determined. Next, to integrate the equations for \( s \) larger than \( 1 \), the range of \( s \) to be calculated is divided into \( k \) parts, and the value of \( \eta_0 \), as a function of \( s \), is approximated by the continuation of inclined line segments as follows:

\[ \xi = \xi_0 + \alpha_j(s - s_j), \quad \xi = \xi_0 + \beta_j(s - s_j), \]  

(16)

\[ j = j + 1, \quad k, \]  

(16a)

\[ \eta_b = \eta_b + \frac{d\eta_b}{ds}, \]  

(16b)

with \( \eta_b = \eta_0 \) at \( s = 1 \). After determining all values at \( s = s_j \), values at \( s = s \), can be integrated as follows: by assuming several values of \( \alpha \) and \( \beta \), the values of \( \eta_1 \), \( \eta_2 \), \( \eta_3 \) and \( \xi \) can be calculated, from which the corresponding values of \( \omega, \nu \) and \( \xi \) are obtained. Then with the help of Eq. (13), Eq. (8) can be integrated from \( s = 1 \) down to \( s = s \), where Eq. (15) holds. Then deduced values of \( \eta_b \), are compared with the assumed values of \( \eta_b \), and by interpolating and further iterating the procedure, the value of \( \eta_b \) at \( s = 1 \) and \( \alpha \), \( \beta \), as well as all values at \( s = s \), are determined. In the following computations, \( \eta_0 \) is assumed to be zero as an approximation.

A-3. Power-law body

In the present section, solutions of the source flow past slender power-law bodies with conical asymptote is treated. The equation of the body considered is given by:
\[ \theta_b = \delta (1 - \frac{1}{s})^{m}, \quad \delta < 1 \]  
(16)

where \( m = 1 \) corresponds to a circular cone. With the above \( \theta_b \) introduced into Eq. (15), we have:

\[ \frac{V_{b}}{(n U)_{b}} = \frac{1}{1 - n'_{b} s (s - 1) / (m n_{b})} \]  
(17)

It is easily shown that at \( s = 1 \), Eq. (17), \( \omega, \mu \) and \( \xi \) reduce to:

\( (V/nU)_{b} = 1, \quad \omega = 0, \quad \mu = (m - 1)/m, \)

\[ \xi = M_{N}^{2}/n_{b}, \quad \text{for} \quad m = 1, \]

\[ \xi = \infty, \quad \text{for} \quad m < 1. \]

The value of \( \xi \) at \( s = 1 \) for \( m = 1 \) cannot be given apriori unless the value of \( n_{b} \) there is known, and must be obtained by an iteration. To accomplish this, first assuming several values of \( \xi \), Eq. (8) is integrated from the shock to the body surface, under the condition that \( \mu = 0 \) and \( \omega = 0 \), then, from the obtained values of \( n_{b} \), Eq. (11), the correct value of \( \xi \) is interpolated so as the relation \( \xi = M_{N}^{2}/n_{b} \) is satisfied. In the case when \( m < 1 \), the value of \( \xi \) at \( s = 1 \) can be assumed as infinity.

For the value of \( s \) greater than unity, the successive approximation described in the preceding section is performed.

Several numerical results for \( m = 1 \) and \( 3/4 \) with \( \gamma = 1.4 \) are shown as follows:

1) Circular cone

The results of cone \( (m = 1) \) with semivortex angle of 15° in a point source flow \( (\theta = 2) \), are shown in Fig. 3 to 6. Figs. 3 and 4 show the values of \( n_{b} \) and \( \xi \) as functions of \( s \) for nose Mach number \( M_{N} = 7.5 \) and \( \omega \). Fig. 5 shows the pressure function \( P \) as the function of \( \eta \) for several values of \( s \) in the case \( M_{N} = 7.5 \). From the figures, it can be seen that \( P \) does not vary so much in between the shock \( (\eta = 1) \) and the body surface \( (\eta = \eta_{b}) \) for each \( s \). Also \( \eta_{b} \) slightly diminishes as \( s \) increases from 1. The pressure coefficient \( C_{p} \) along the cone surface referred to the free stream pressure \( P_{1} \) is given by:

\[ C_{p} = \frac{P_{b} - P_{1}}{\rho_{N} U_{N}^{2}/2} \]

\[ = \frac{2 (\tan^{2} \alpha) P_{b}}{\eta_{b}^{2} (1 - s (s - 1) \eta_{b}^{2}/\eta_{b}^{2}) - \frac{2}{\gamma M_{N}^{2} s^{2} \alpha}} \]  
(18)

Therefore, in the case of \( M_{N} = \infty \), if \( P_{b} \) and \( \eta_{b} \) are taken as their mean values with \( \eta_{b} \) neglected, then \( P_{b} \) is proportional to \( s^{-1} \). Figs. 6a and 6b show the pressure pressure distributions along the cone surface when \( M_{N} = 7.5 \), and \( \omega \), showing the large variation of \( C_{p} \) as \( s \) increases. Such a large variation of pressure along the surface demonstrates that the power series expansion of flow quantities in powers of \( (s - 1) \) is inadequate beyond \( s > 1.1 \).

For comparison, the Newtonian pressure distribution corresponding to \( M_{N} = \infty \) is calculated as follows. In this case, the pressure on the surface at radial distance \( r \) is given by:

\[ P_{b} = \rho_{n} U_{n}^{2} \sin^{2} \alpha \]

where \( \alpha = \theta - \theta_{w} \), \( r \sin \sigma = r_{n} \sin \alpha \). Therefore when \( \theta_{w} < 1 \),

\[ P_{b} = \frac{4}{\alpha} U_{n}^{2} \sin^{2} \alpha \]

That is, the pressure is proportional to \( s^{-1} \). Fig. 6b shows also the result for \( M_{N} = \infty \) obtained by Gorgui for \( \gamma = 1.4 \), and the one calculated by the Newtonian approximation. The present results essentially coincide with Gorgui's one near the nose region \( (s = 1.1) \). The present result and the Newtonian one for \( M_{N} = \infty \) show essentially a good comparison for a wide range of \( s \) \( (s = 1.2) \).

2) 3/4 power-law body

This corresponds to the body shown in Eq. (16) with \( m = 3/4 \), which has the 3/4 power-law body near the nose, and approaches a cone asymptotically as \( s \) increases. Calculating procedure is almost the same as 1) except the nose point \( s = 1 \). Figs. 3 and 4 show the values of \( n_{b} \) and \( \xi \) as functions of \( s \) for \( M_{N} = 7.5 \). Fig. 7 shows the pressure distribution along the surface.

I-B. Linearized theory

In hypersonic flows, most of the important problems require non-isentropic, non-linear treatments. However, if the body is very slender in the sense that the effective hypersonic surface parameter \( \chi \) (the product of the local free stream mach number \( M_{1} \) and the angle \( \theta \) of the body surface with respect to the local free stream direction), is smaller than unity, the flow field can be assumed as isentropic with good accuracy, and the supersonic potential flow theory is applicable. Further, the perturbed equation can be linearized when \( \chi \) is moderately smaller than unity.

In the present section, the source flow over a very slender body of revolution is discussed by a linearized perturbation theory.

In the polar coordinates system \( (r, \theta) \), the basic equations of the axisymmetric flow over a pointed body of
revolution, are given by Eq. (5). It is assumed that $\chi = M_1 \varepsilon$ is smaller than unity, which implies that $\Theta$ in the disturbed flow field is very small everywhere. Because the flow is assumed to be isentropic, there exists a velocity potential $\Phi$ defined by:

$$u = \frac{\partial \Phi}{\partial r} \varepsilon \Phi_{r}, \quad v = \frac{\partial \Phi}{\partial \theta} = \frac{1}{r} \frac{\partial \Phi}{\partial \theta} \varepsilon \Phi_{\theta}$$  \hspace{1cm} (19)

Then the gas dynamic equation is derived from Eq. (5) and (19) as follows:

$$\frac{\Phi_{rr}}{(1-\varepsilon) \frac{1}{r^2} + \frac{\Phi_{\theta\theta}}{(1-\varepsilon) \frac{1}{r^2}}} - \frac{2\Phi_{r} \Phi_{\theta} \Phi_{r\theta}}{r^2 a^2} + \frac{\Phi_{r}}{r} \frac{\Phi_{\theta}}{r} \frac{1}{2} a^2 
\frac{\Phi_{\theta}}{r} \frac{\Phi_{\theta}}{r} + \Phi_{r} \frac{\Phi_{r}}{r} \frac{1}{2} a^2 = 0. \hspace{1cm} (20)$$

Here, the square $a^2$ of the local sound speed takes the form:

$$a^2 = (\gamma - 1) \frac{H - \frac{\Phi_{rr}}{2} \frac{1}{r^2}}{2 \varepsilon}$$

where

$$H = \frac{\gamma p}{\gamma - 1} + \frac{1}{\gamma - 1} (u^2 + v^2) \text{ const.}$$

$\Phi$ is divided into free stream and perturbation potentials $\Phi_0$ and $\Phi_1$ by:

$$\Phi(r, \theta) = \Phi_0 (r) + \Phi_1 (r, \theta)$$

$$u = \frac{\Phi_r}{r} \Phi_0 + \frac{1}{r} \Phi_{rr}, \quad v = \frac{\partial \Phi_{\theta}}{\partial \theta} = \frac{1}{r} \Phi_{\theta} \Phi_{rr} \frac{1}{r} \Phi_0 \Phi_{\theta} \Phi_{\theta}$$  \hspace{1cm} (21)

It is assumed that the body is very slender and the perturbed velocity components are very small compared with the free stream velocity such that:

$$\Phi_0 > \Phi_1 \varepsilon \frac{1}{r} \Phi_{\theta} \Phi_{\theta}$$

Then after higher order terms than $O(v/a)$ are neglected, Eq. (20) is reduced to:

$$(1 - M_1^2) \Phi_{rr} + \frac{2 \Phi_0 r}{r} = 0,$$

$$(1 - M_1^2) \Phi_{rr} + \frac{2 \Phi_{rr} (2 + (\gamma - 1) M_1^2)}{r (1 - M_1^2)} = 0,$$

$$\Phi_{\theta\theta} + \frac{2 \Phi_{\theta\theta}}{r^2} + \frac{2 \Phi_{\theta\theta}}{r} + \frac{\Phi_{\theta\theta}}{r^2} = 0. \hspace{1cm} (22)$$

where $M_1$ can be approximated by:

$$M_1 = M_N s^{-1}$$

If the non-dimensional variables $z$ and $\omega$ are introduced by:

$$z = s^{-1} (\gamma - 1)/(\gamma - 1), \quad \omega = M_N s$$

then with the aid of Eq. (23), the perturbation equation Eq. (22) for $\Phi_1$, is transformed into:

$$\Phi_{1zz} + \frac{2}{z} \Phi_{1z} - \Phi_{1\omega \omega} = 0, \hspace{1cm} (25)$$

where

$$k = (2 - \gamma)/(\gamma - 1).$$

Further, when $\psi$ is introduced by:

$$\Phi_1 = \psi / z,$$

then Eq. (25) is transformed into:

$$\Phi_{zz} + \frac{2-k}{z} \Phi_{z} - \Phi_{\omega \omega} = 0. \hspace{1cm} (27)$$

Eq. (25) is solved by Yasuhara et al. for $\gamma = 2 (k = 0)$ and $\gamma = 1.5 (k = 1)$, using the method of source distribution. While if $\gamma = 4/3$, then $k = 2$ and Eq. (27) has the same form as Eq. (25) for $k = 0$. The general solution of $\Phi$, for a pointed body with $\gamma = 4/3$ can be expressed as follows:

$$\Phi_1 = \frac{1}{\eta \eta + \omega} \frac{h(\eta_1) \eta_1 \eta_{1\omega}}{\eta_{1\omega}} \int_0^{\eta_1} \frac{1}{\eta_{1\omega}} \frac{h(\eta_1 + \omega \cos \theta) d \omega}{h(\eta_1 + \omega \cos \theta) d \omega}$$

$$\eta = 3 s^{1/3}, \hspace{1cm} (28)$$

where $h(\eta_1)$ denotes the source distribution function along the body axis, to be determined from the surface condition. The boundary condition along the body surface gives that:

$$(\psi / z)_b = (v/u)_b = rd \delta_b / dr,$$

or

$$\Phi_{1\omega} = - \frac{u_N s N M_1^2}{M_N^2} \frac{d \omega}{d \eta},$$

where $u_N$ is the free-stream velocity at the nose of the body.

The pressure coefficient $C_p$ referred
to the free-stream pressure $p_0$ at the nose is given by:

$$C_p = (p_b - p_0) / (\rho_0 u_0^2 / 2) \tag{30}$$

The perturbed pressure coefficient $C_{pl}$ referred to the local free-stream pressure $p_1$ is, within the present approximation, expressed by:

$$C_{pl} = (p_b - p_1) / (\rho_0 u_0^2 / 2)$$

$$= -\frac{1}{s^2} \left( \frac{\phi}{u_N} + \left( \frac{\phi}{u_N} \right)^2 \right) \frac{(\frac{\phi}{u_N})^2}{u_N} \tag{31}$$

Practical methods of solution for $\gamma=4/3$ are almost the same as given in Ref.10.

Fig.8 shows the calculated pressure distribution along the very slender cone with the semi-vertex angle $\alpha=4^\circ$ when $M_{e}=7.5$. Also shown in the figure are the results when $\gamma=2.0$ and 1.5 obtained in Ref.10, respectively. All these curves are close enough, and this shows that the pressure distribution expressed in the form $C_{pl}$ is, practically not sensitive to the difference in the value of $\gamma$. However, if it is expressed in the form $C_p$, then appreciable differences can be seen as shown in Ref.10.

I-c. Equivalency between source and parallel flows for $\gamma=2$.

As shown shortly in Ref.7, there is some one-to-one correspondence relation between source flow problem and parallel one in inviscid, hypersonic small disturbance theory, provided that $\gamma=2$.

According to this relation, the problem for the power-law cone in a hypersonic source flow expressed by the polar coordinates $\theta_0 = \phi (1-1/s)^2$, is equivalent to the one for the power-law body in the parallel flow expressed by the cylindrical coordinates $\gamma_0 / L = \phi (x/L)^2$. If the problem for the parallel flow with the free stream Mach number of $M_0$ is solved, the pressure coefficient $C_{pl}(x/L; M_0, \gamma)$ is expressed in terms of $x/L$. Then, the corresponding pressure coefficient $C_{pl}$ referred to the free stream pressure $p_0$ in the source flow with the free stream nose Mach number of $M_0$, can be related to $C_p$ through the simple conversion relation:

$$C_{pl}(s; M_0, \gamma) = C_p \left( 1 - 1/s \right) M_0, \gamma / s^2 = C_p / s^2 \tag{32}$$

provided that $\gamma=2$. In the above, $x/L$ in the expression of $C_{pl}$ for the parallel flow is replaced by $1-1/s$.

Now, although the above value of $\gamma(=2)$ is different from that for actual gases, if the coefficient $C_p$ in the parallel flow is not much sensitive to such a difference of $\gamma$, as shown in Lees and Kubota's analyses (Ref.11, 12), then $C_{pl}$, for the source flow with $\gamma$, can be obtained from $C_p(x/L; M_0, \gamma)$, by simply dividing it by $s^2$, in which $x/L$ should be replaced by $1-1/s$, that is:

$$C_{pl}(s; M_0, \gamma) = C_p \left( 1 - 1/s \right) M_0, \gamma / s^2 \tag{33}$$

In the above conversion, it is assumed that the term $C_p$ on the right-hand side is also insensitive to the difference of $\gamma_0$ in the source flow problem. In Figs.6 and 7, the pressure distributions along the cone and the 3/4 power-law nosed cone, calculated by applying the above equivalence relation are shown. The equivalence results and the quasi-similarity results show good comparisons as a whole.

II. Experiments

II-A. Shock tunnel and test conditions.

Experiments on hypersonic source flows over long slender cone, 3/4 power-law body and hemisphere cylinder, etc., are performed in a conical nozzle of the shock tunnel at the Nagoya University. The Mach number $M_0$ of the free stream at the nose of bodies is fixed to 7.5, and surface pressures are measured and compared with the above theories. The details of the tunnel are shown in Ref.13, and therefore shortly described here.

The tunnel consists of the driver tube (200mmx5302mm), the driven tube (100mm x9998mm), the conical nozzle (10° semi-vertex angle with throat and exit diameters of 13mm and 300mm), and the dump tank (1450mm x 6125mm). The initial pressures of the driver, driven tube and the dump tank are fixed to 41.0kg/cm², 1.03kg/cm², and 0.1 torr, respectively.

The configuration of the nozzle and test section is shown in Fig.9. Air is used as the working gas.

The models employed are shown in Fig.10. Each pressure hole on a model surface (1.5 or 2.0mm) is connected to a piezo resistance type pressure gauge directly, or through a 1.5mm lead-pipe. The pressure $p_0$ in the stagnation region just upstream of the nozzle is measured by the Kistler gange. The impact pressure probe is used to measure the distribution of the impact pressure $p_1$ along the nozzle axis. Fig.11 shows an example of time traces of $p_0$ and $p_1$. The traces show very similar patterns, with the first transient duration having pressure rise and slight fall, followed by
the second constant pressure, which is regarded as the testing time range, and then further pressure fall after about 70ms from the onset of pulse. From the measured values of $p_a$ and $p_t$ in the testing time range at several axial positions $x$, the distribution of the free stream Mach number $M_\infty$ and the corresponding effective area ratio $A/A^*=(r/r^*)^2$ or its square root $r/r^* (r$ is the radial distance from the effective source, and $^*$ denotes the effective throat condition), are computed, and $r/r^*$ is plotted against $x$ in Ref.14. This $x-(r/r^*)$ relation was shown to be straight approximately, which means that the flow in the present conical nozzle can be assumed to be a source flow.

II-B Distributions of surface pressures.

Although experimental pressure distribution on the cone against $s=r/r^*$ was reported in Ref.14, this is again shown as well as the new results on the 3/4 power-law nosed cone. The pressure coefficient $C_p$ is referred to the local free stream pressure $p_f$, that is:

$$C_p = \frac{p_f - p_l}{\rho N_N^2 N_N^2/2}$$

Figs.6a and 7 show the experimental pressure coefficients $C_p$ against $s$ for the cone and the 3/4 power-law body in the source flow with the free stream Mach number $M_\infty$ at the nose of 7.5, respectively. Also shown in these figures are inviscid, theoretical results obtained by the present quasi-similarity approximation for $\gamma=1.4$, and also ones obtained by applying the extended parallel-source equivalence for power-law bodies. Comparisons between theories and experiments give essentially good correspondence except some discrepancies caused by the viscous effects, which were not considered in the present theories, and by experimental errors, as well as by errors included in the present empirical assumption.

Conclusions

First, the inviscid, hypersonic quasi-similarity theory is applied to a long body in a source flow, and practical calculations for a cone and a 3/4 power-law body are given. Second, the linearized theory for a very slender pointed body is treated by the method of source distribution, and the results for a very slender cone in the source flow with $\gamma=1.5$ and $4/3$ are time range, showing close coincidences each other. Third, the one-to-one correspondence between source flow and parallel one for power-law-bodies when $\gamma=2$, is extendedly applied to the case for any $\gamma$, under the empirical assumption that the pressure coefficient in the flow is insensitive to the difference of $\gamma$. Last, experiments on the source flow over a long cone and a 3/4 power-law body in the conical nozzle of a hypersonic shock tunnel are described, and the measured pressure distributions are compared with the above theories, giving essentially good coincidences except discrepancies caused by the viscous effects (which are not considered in theories) and experimental errors.
